

BASIC Stamp® HomeWork Board™

#29158 10-pack

Introduction

It's not often that we start technical documentation with a bit of marketing punch. If you like the low cost of a BASIC Stamp Rev. Dx (retails ~\$34) and the idea of a half-price BASIC Stamp 2 / Board of Education (retails ~\$100) then the BASIC Stamp HomeWork board is the ticket for your classroom. This is the least expensive way to get a large educational group started with the BASIC Stamp microcontroller.

The HomeWork Board was created specifically for educators to send home with students with these uses in mind:

- BASIC Stamp-related homework assignments
- Dedicated science-fair, contest or hobby projects
- Students who express personal interest in further developing their BASIC Stamp projects but can't have their own Board of Education / BS2 due to its higher cost.

Since it is less expensive than the Board of Education / BS2 module, can the board be used for Stamps in Class experiments? Most likely, with the following considerations:

- Servo connection ports for robotics are not included on the HomeWork Board platform. It's possible to use male/male headers for servo connections with a second power supply jumpered to the HomeWork Board to control servos.
- 220 ohm resistors are built into each of the 16 I/O pins for current protection so the PBASIC interpreter cannot be easily damaged. This protects the BASIC Stamp from over-current conditions but also slightly changes the behavior of the Stamps in Class experiments when certain commands are used, such as RCTIME.
- In some Stamps in Class texts, circuit pictorials may not match the HomeWork Board. Most Stamps in Class texts are HomeWork Board compatible, and some include alternative wiring diagrams or other notations where needed. You may check the recommendations in each Stamps in Class text or refer to the Stamps in Class program overview flowchart at www.parallax.com.
- Power supply is from a 9V battery, not the wall pack.
- Current supply from the on-board regulator is limited to 500 mA (Rev C and D) and 50 mA (Rev A and B), versus the Board of Education's 1 amp or more.

However, these cost-reducing limitations do not limit the use of the HomeWork Board for most projects. In fact, the minimalist design is simple to use and entirely flexible for most projects.

Package Contents

The BASIC Stamp HomeWork Board is sold separately only in quantities of 10. The reason for this is that the board is intended for the educational market only, to be purchased by educators for use in their classrooms. The kit includes only the boards – nothing else. However, a single HomeWork Board is included as part of the BASIC Stamp Activity Kit, (#90005) which is the most economical complete kit to learn BASIC Stamp programming.

BASIC Stamp HomeWork Board Hardware Design

The HomeWork Board uses the BASIC Stamp 2 surface-mounted directly to the printed circuit board. The BASIC Stamp 2 has a wide variety of available support hardware, code examples and applications. Furthermore, it performs most of the same functions of the newer BASIC Stamp models though with less speed and memory. The BASIC Stamp 2's technical specifications are shown below (Table 1). Also review the hardware (Figures 1 and 2) and schematic (Figure 3).

Table 1

BASIC Stamp
HomeWork Board
Specifications

Microcontroller	Rev A, B, C: PIC16C57 surface mount Rev D: PIC16F57 surface mount
Speed	20 MHz / ~4,000 instructions per second
EEPROM	2K bytes (program and data)
Program Length	~500 to 600 lines of PBASIC
RAM (variables)	32 bytes (6 for I/Os and 26 for variables)
Input / Outputs	16 (up to 17 RS-232 communication ports)
On-board BS2 per I/O Source / Sink Current:	20 / 25 mA (40 / 50 mA per 8 I/O pins)
Vdd Source Current	Rev A, B: 50 mA Rev C, D 500 mA
Serial Communication	300-50K baud I/O; DB9 Female connector
Current Requirements	7 mA running, 50 μ A in sleep
PC Interface	Serial port, DB9
Power Supply	5 V through 50 mA regulator (Rev A, B) or 500 mA regulator (Rev C, D) from a 9V transistor battery
Environment:	32 to 158° F (0 to 70° C), 70% non- condensing humidity
HomeWork Board Size	3" x 4"
Project Area	Built-in breadboard: two 5-socket row x 17 column, 0.1 inch spacing

- A. **BASIC Stamp 2 Module:** The BASIC Stamp microcontroller is comprised of several components: a Microchip PIC 2K 8-bit microcontroller programmed with the BASIC Stamp Interpreter that runs the Parallax BASIC Stamp code like a mini operating system; a 2K EEPROM with a user-modifiable read-only memory (ROM) that can be reprogrammed with your BASIC Stamp code; a 20 MHz resonator to provide an accurate clock source for the BASIC Stamp. On the HomeWork Board we also added 220 Ω resistors across the I/O pins to provide some current protection from wiring mistakes; a voltage regulator which provides 500 mA (Rev C, D, but 50 mA for Rev A, B) for the BASIC Stamp and your circuits powered from the breadboard's Vdd connection.
- B. **DB-9 Female:** The DB-9 port connects via serial cable to your PC's serial port. This port is used to download programs to your BASIC Stamp and for the BASIC Stamp to send data back to the PC.

- Figure 3

Power Consumption and Battery Life

Parallax normally designs BASIC Stamp carrier boards with power jacks for wall transformers. Wall transformers provide plenty of power but they are not as portable for science fairs, robots and environmental datalogging. Considering that the BASIC Stamp draws only small amounts of current it could be deployed in a remote location and run from a battery for a long time.

The BASIC Stamp has commands for reduced power consumption, but what about a power indicator LED? It could drain the battery in a day or two by itself if being used to indicate a power supply! LEDs consume current, typically 10-12 mA. Removing the LED wasn't an option since it discloses the common technical support problem of a missing power supply.

The solution was to connect a Running Indicator LED to the "clock" line of the BASIC Stamp EEPROM. The EEPROM's clock line is active only when the BASIC Stamp is actually running a program. Moreover, the BASIC Stamp HomeWork Board's Running Indicator LED is a low current LED consuming only about 2 mA.

Milliamp hours is a statistic measuring the amount of energy stored in a battery. For example, if you have a 1 mA-hr battery and a project drawing 0.5 milliamps, the battery will last for two hours. A typical 9V Duracell alkaline transistor battery provides about 565 milliamp hours of energy.

If the BASIC Stamp is being used in a project where at least some small amount of time is spent doing nothing you can put it in a low-power mode to extend battery life using the SLEEP command (Table 2). The duration which you put the BASIC Stamp to SLEEP is accurate to $\pm 1\%$ at 75° F and can range from 2.3 seconds to 18 hours (you can "wake up" and go back to sleep after 18 hours). By comparison, the PAUSE command is simply a delay in a PBASIC program yet the BASIC Stamp continues to draw full operating current. See the BASIC Stamp Windows Editor on-line help for all the details on the SLEEP and PAUSE commands.

Table 2 BASIC Stamp 2 and Power LED current draw during different modes of operation.		BASIC Stamp Current Draw	Power LED Current Draw	Possible Battery Life
	PAUSE Mode	8 mA	2 mA	(565 mAh/10 mA) = 56.5 hours
	SLEEP Mode	40 μ A	0 mA	(565 mAh/(40 μ A/1000 mA) = 14,125 hours

Note: 1 mA is 1/1,000th of an Amp. 1 microAmp (μ A) is 1/10,000th of an Amp.

Maybe putting a BASIC Stamp to SLEEP permanently only demonstrates that a 9V battery can last almost two years if you wake the BASIC Stamp once in a while. In reality, projects need to wake up and provide current to "loads" like LEDs and other chips used in your project. If you know the current draw of the individual components and how long they are activated you can make an educated guess at total current consumption and battery life. If you're only visiting your North Pole weather station annually even a small battery can provide a long lifespan for the BASIC Stamp, not to mention larger batteries with more milliamp hours.

To clarify the different power consumption operating scenarios and their effects on battery life review the following two programs in conjunction with Table 2.

Both example programs below have the same result. The BASIC Stamp will send numbers to the BASIC Stamp Editor's Debug Terminal and then go into a period of inactivity for one second. With the PAUSE example the Running Indicator LED remains on because the EEPROM is still communicating with the BASIC Stamp interpreter chip, but with the SLEEP example the EEPROM is shut down and the Running Indicator LED is off.

With this first example the Running Indicator LED remains on when the PAUSE command is executed. Current consumption remains at 10 mA.

```
' POWER DEMO - PAUSE.BS2
' Demonstrates the Running Indicator LED behavior with the PAUSE command
' {$STAMP BS2}
' {$PBASIC 2.5}

' Variable definition
loopCounter VAR Byte

' Main Program
DO
  FOR loopCounter = 0 TO 99
    DEBUG HOME, "loopCounter =", DEC loopCounter
  NEXT
  PAUSE 1000
LOOP
```

With the SLEEP example the Power LED turns off when the SLEEP command is being executed because the EEPROM is inactive. Current consumption is 10 mA while the loop is being executed but drops to 40 µA during the SLEEP command.

```
' POWER DEMO - SLEEP.BS2
' Demonstrates the Running Indicator LED with SLEEP command
' {$STAMP BS2}
' {$PBASIC 2.5}

' Variable definition
loopCounter VAR Byte

' Main Program
DO
  FOR loopCounter = 0 TO 99
    DEBUG HOME, "loopCounter =", DEC loopCounter
  NEXT
  SLEEP 1
LOOP
```

Precautions

Be alert to static-sensitive devices and static-prone situations. The BASIC Stamp, like other integrated circuits, can be damaged by static discharge that commonly occurs by touching grounded surfaces or other conductors. Environmental conditions (humidity changes, wind, static-prone surfaces, etc) play a major role in the presence of random static charges. It is always recommended to use grounding straps and anti-static or static dissipative mats when handling devices like the BASIC Stamp. Since you don't have a dissipative mat, touch a grounded surface after you have approached your work area. This isn't as critical as you might think but being prudent only protects your hardware.

→ Before building circuits, disconnect the battery!!

Quick Start Programming Guide

You can find a quick-start guide for connecting the HomeWork Board to the PC and testing the programming connection in the first two chapters of "What's a Microcontroller?" This fully HomeWork Board-compatible Stamps in Class book is available as a free PDF download from www.parallax.com.
