

50 kSps, 24-bit, High-throughput $\Delta\Sigma$ ADC Evaluation Board

Features

- ❑ Two Analog Input Channels Multiplexed to the CS5560 ADC
- ❑ Pre-configured to require a minimum number of external connections to your data acquisition system.
- ❑ All functionality accessible through the connector interface and board-level options.
- ❑ On-board 4.096 V Reference
- ❑ Pre-configured for Master mode SPI™ communication to a data capture system.

General Description

The CDB5560 is a versatile tool designed for evaluating the functionality and performance of the CS5560 ADC (Analog-to-Digital Converter). The SPI serial port on the CDB5560 evaluation board is configured in Master mode and will start transmitting data after power-up upon reset. This evaluation board is designed to connect to your data capture system or will interface to the CapturePlus II data acquisition system available from Cirrus Logic.

The CS5560 delta-sigma ADC produces fully settled conversions to full specified accuracy at 50 kSps. This ability to produce fully settled conversions for every sample makes it suitable for converting multiplexed input signals. To help evaluate this feature, the CDB5560 includes two differential analog inputs multiplexed into the CS5560. The multiplexer can be switched at the CS5560 ADC sample speed and the ADC will produce fully settled conversion data for each input channel.

All evaluation board functionality for evaluating the CS5560 ADC is accessed through the connector interface and board-level options.

Schematics in PADS™ PowerLogic™ format are available for download at:

1. INTRODUCTION

The CDB5560 evaluation board is a platform for evaluating the CS5560 ADC performance. The evaluation board is designed to connect to the SPI serial port of a processor or data capture system or will interface directly to the CapturePlus II data acquisition system available from Cirrus Logic. The CapturePlus II data acquisition system is a powerful integrated hardware/software tool designed to fully exercise the CDB5560 and other Cirrus Logic evaluation boards.

The CDB5560 evaluation board is designed to simplify the hardware setup required to evaluate the CS5560. Interfacing the CDB5560 evaluation board to a user-supplied data capture system can be as simple as connecting the SPI port and using the CDB5560 default hardware configuration. In this configuration simply press the Reset switch on the CDB5560 and it will automatically begin transmitting data to the data capture system.

All evaluation board functionality for evaluating the CS5560 ADC is accessed through the connector interface and board-level options.

The CS5560 delta-sigma ADC produces fully settled conversions to full specified accuracy at 50 kSps. The ability to produce fully settled conversions for every sample makes it suitable for converting multiplexed input signals. To help evaluate this feature, the CDB5560 includes two differential analog inputs multiplexed into the CS5560. The multiplexer can be switched at the CS5560 ADC sample speed and the ADC will produce fully settled conversion data for each input channel.

For detailed information on the CS5560 ADC, please reference data sheet DS713 at www.cirrus.com.

1.1 Overview

The CDB5560 evaluation board has both analog and digital circuit sections. The analog section consists of the CS5560 ADC, two analog input signal buffers, controlled through a multiplexer, that condition the signals into the ADC, and a precision 4.096 V reference. The digital section consists of board operation configuration control signals, reset circuitry, an SPI™ serial port, a jumper connection for initiating ADC calibration, and an EEPROM for evaluation board identification.

The evaluation board operates from +2.5V, -2.5V, +3.3V and communicates through an SPI™ serial port.

Figure 1 illustrates the CDB5560 block diagram.

Figure 1. CDB5560 Block Diagram

2. QUICK START

NOTE: Shaded boxes marked with "OPT. CONFIG." are not necessary for operation in an end user product.

Figure 2. CDB5560 Board Layout

The CDB5560 evaluation board is designed to interface with a data acquisition system. To connect and configure the CDB5560 perform the following initialization procedure:

1. Verify that the power supplies are off.
2. Connect the power supplies to the CDB5560 as shown in Table 1 on page 7.
3. Verify that the power is off to the analog input signal & control signal sources.
4. Connect the analog input signal sources to the evaluation board per Table 2 on page 7. Verify from Table 4 on page 9 that the analog input channel selected is INPUT A.
5. Configure the CDB5560 by connecting the control signal sources to the evaluation board as shown in Table 3 on page 9. Apply logic-level inputs as required to override the resistor pull-ups/pull-downs.
6. Make connections to the SPI™ serial port connector as shown in Table 5 on page 9. The CS5560 ADC serial port is configured by default to operate in the SSC (Synchronous Self Clocking) mode. Refer to the CS5560 data sheet for more information on serial communication modes and signal timing.
7. Turn on the power supplies to the evaluation board.
8. Apply power to the signal source.
9. Press the Reset switch on the evaluation board.
10. The CS5560 ADC's SPI™ serial port should now be communicating data.

3. HARDWARE DESCRIPTION

3.1 Absolute Maximum Ratings

Observe the following limits to ensure the CDB5560 component ratings are not exceeded.

- **CS5560**
 - The absolute maximum supply voltage that can be applied to the +3.3V power supply connection is +3.6V.
 - The absolute maximum power supply voltage that can be applied between pins VL and V1- is 6.1 V.
- **LMP7732**
 - The absolute maximum power supply voltage that can be applied between the +2.5V and -2.5V power supply connections is +5.5V.

3.2 Power Supply

Power supply connections and requirements are specified in Table 1. below.

Table 1. Power Supply Connections

Power Supply Requirement	Power Supply Connection	Associated Ground Return	Associated Test Points
+2.5 V DC, $\pm 5\%$, <50 mA	E5	E3	TP2, TP1 (GND)
-2.5 V DC, $\pm 5\%$, <50 mA	E9	E7	TP4, TP3 (GND)
+3.3 V DC, $\pm 5\%$, <50 mA	E16	E13	TP6, TP5 (GND)

Important: It is recommended that all power supplies be isolated from utility ground to prevent the introduction of a ground loop. One ground connection may already exist through the serial port connection to utility ground. Using the Cirrus Logic CapturePlus II system simplifies making connections to the CDB5560 by providing electrical isolation between the two.

Using twisted/shielded wire will reduce electrical noise induced onto the power supply cables.

Power supplies are to be adequately regulated and sufficiently low noise to meet the application requirements.

3.3 Analog Section

3.3.1 Analog Input Buffers

The analog input signal connections to the input buffers are made at the INPUT A and INPUT B connectors, as specified in Table 2.

Table 2. Analog Input Connections

Channel	Analog Input Connection	Differential Input Signal Voltage Range	Impedance
INPUT A	J4	-4.096 V to +4.096 V	50 Ohms
INPUT B	J5	-4.096 V to +4.096 V	50 Ohms

There are two analog input channels on the evaluation board. National Semiconductor LMP7732 Each analog input channel consists of two low-noise amplifiers configured as unity gain non-inverting buffers. The buffers utilize two National Semiconductor® LMP7732 precision, low-noise, low-voltage, dual op-amps. These op-amps enable both the inputs and outputs of the analog input buffer to operate virtually rail to rail. The channel input impedance is 50 Ohms.

For detailed information on the LMP7732 precision industrial op-amps, please visit National Semiconductor's website at www.national.com.

The analog inputs are designed for connections to differential input signals. The usable input voltage range is -4.096 V to +4.096 V. The theoretical input frequency range of the CS5560 is from DC to the Nyquist frequency of 25 kHz. The analog input buffer amplifiers are configured for a cutoff frequency of 16.8 kHz to band-limit noise into the ADC. Changing the cutoff frequency will change the noise bandwidth accordingly.

3.3.2 Multiplexer

Analog input channel selection is controlled through the multiplexer. The multiplexer is configured with a pull-down resistor on the MUX control line to enable input channel labeled "INPUT A" by default. To select channel B, apply 3.3 V to the multiplexer input control line (MUX).

Signal levels for controlling the multiplexer that selects between analog input channels A and B is shown in Table 3.

Table 3. Analog Input Channel Selection

Multiplexer Control Input (MUX)	Input Channel Enabled
0 V	A
3.3 V	B

During multiplexing, the maximum sample rate for each channel is half that of the ADC's maximum sample rate. Additionally, the Nyquist frequency for each channel is half of the ADC's Nyquist frequency.

3.3.3 ADC Reset

The CS5560 ADC makes use of an externally generated power-on reset. Therefore, after power is applied to the ADC, the reset pin must be driven low then released. Pressing the Reset button generates a reset cycle. A reset cycle can be generated at any time during ADC operation. The ADC RST pin (active low) is held inactive through a pull-up resistor.

3.3.4 Voltage Reference

The voltage reference IC provided generates a 4.096 V precision reference.

3.3.5 ADC Reference Frequency

The reference frequency for the CS5560 ADC is provided by a 16.000 MHz oscillator.

3.4 Digital Section

3.4.1 Hardware Configuration

The CDB5560 evaluation board hardware comes pre-configured so the only connection required between it and a data acquisition system is the serial port connection.

The hardware setup is reconfigurable through the hardware control interface connectors. Configure the evaluation board by setting the appropriate control line to the appropriate logic level.

Table 4. Hardware Configuration Signals

Function	Default Level	Label	Connector	Test Point
Input Channel Select	INPUT A = Selected (Low)	MUX	J6, Pin 16	J3, Pin 2
Analog Input Buffers	Buffers = Enabled (High)	BUFEN	J1	J3, Pin1
Serial Port Mode	Sync. Self Clock = Enabled (High)	SMODE	J6, Pin 12	J3, Pin 3
Data Ready Flag	Data Ready When Set (Low)	$\overline{\text{RDY}}$	J8, Pin 10	J3, Pin 4
Reset	Reset = Inactive (High)	$\overline{\text{RST}}$	J6, Pin 6; S1	J3, Pin 6
Self Calibration Mode	Calibration = Inactive (Low)	CAL	J6, Pin 8; J2	J3, Pin 7
Bipolar / Unipolar Mode	Bipolar = Enabled (High)	BP / $\overline{\text{UP}}$	J6, Pin 2	J3, Pin 8
Sleep Mode	Sleep = Inactive (High)	$\overline{\text{SLEEP}}$	J6, Pin 4	J3, Pin 9
Serial Port Communication	Chip Select = Enabled (Low)	$\overline{\text{CS}}$	J8, Pin 2	E23
Data Conversion Mode	Continuous Conversion = Active (Low)	$\overline{\text{CONV}}$	J8, Pin 12	E21

3.4.2 SPI™ Serial Port Communications

The CS5560 ADC communications port features an SPI™ serial port. It can be configured for SSC mode (Master) or SEC mode (Slave) mode as shown in Table 4. Test points are provided to monitor serial communications.

Connections to the serial interface are made according to the following table.

Table 5. Serial Interface Connections

Function	Label	Connector	Test Point
Chip Select	$\overline{\text{CS}}$	J8, Pin 2	E23
Serial Data Input	SDI	J8, Pin 4	E24
Serial Data Output	SDO	J8, Pin 6	E25
Serial Clock	SCLK	J8, Pin 8	E26

APPENDIX A. MAXIMIZING THE PERFORMANCE OF THE CS5560

A.1 PCB Layout Considerations

- Keep the signal path short between the CS5560 ADC input capacitors C20, C28, C37, C44 and the ADC input pins to minimize trace inductance.
- The analog input buffer amplifiers and ADC input buffer capacitors are placed before the multiplexer. Placing the buffer amplifiers before the multiplexer allows the amplifiers driving the ADC buffer capacitors to be fully settled when sampled by the ADC. Therefore, the multiplexer must be of a low on-resistance type to prevent distortion or latency issues.
- Power supply noise is a major design consideration and the power supplies need adequate bypassing and bulk capacitance.
- When operating the ADC from +2.5 V and -2.5 V split supplies, place the power supply & buffer amplifier bypass capacitor ground connections close together.
- Keep all ground connections on each differential buffer amplifier as close to the device as possible to avoid introducing differential noise through high-impedance connections.
- Keep trace lengths short between the ADC and the voltage reference IC negative supply pins.
- Route the oscillator output away from analog circuitry.
- Use a solid ground plane in the PCB layout.
- Provide adequate separation between analog and digital signals.
- To minimize distortion within the analog signal path, consider using components with smaller voltage dependencies.
- Minimize ADC digital output edge transition current loading.

A.2 Hardware Considerations

At a system level, use shielded cable for interconnects. Keep interconnect cable lengths as short as possible. Route analog and digital signals connecting to the PCB away from each other.
