

CS4122

Triple Air-Core Gauge Driver with Serial Input Bus

The CS4122 converts digital data from a microprocessor to complementary DC outputs and drives air-core meter movements for vehicle instrument panels. It is optimized for one 360° gauge and two 112° gauges. The digital data controls the voltage applied to the quadrature coils of the meters with a 0.35° resolution for the major (360°) gauge and 0.44° resolution for the minor (112°) gauges. The accuracy is $\pm 0.75^\circ$ for the major and $\pm 1.00^\circ$ for the minors. The interface from the microcontroller is by a SPI compatible serial connection using up to a 2.0 MHz shift clock rate.

The digital code is shifted into the appropriate DAC and multiplexer. These two blocks provide a tangential conversion function to change the digital data into the appropriate DC coil voltage. The major gauge driver can position a pointer anywhere within a 360° circle while the minor gauge drivers are limited to an arc of 112.2°.

The output buffers are capable of supplying up to 70 mA per coil and are protected against output short circuit conditions. A thermal protection circuit limits the junction temperature to approximately 160°C.

A fault output lead goes low when any of the outputs are shorted or the device is in a thermal shutdown state. This ASIC is designed on POWERSENSE™ 3.0.

Features

- Serial Input Bus
- 2.0 MHz Operating Frequency
- Independently Addressable Gauges
- Tangential Drive Algorithm
- 70 mA Drive Circuits
- 0.75° Major Accuracy
- Power-On-Reset
- Protection Features
 - Short Circuit
 - Overtemperature
- Internally Fused Leads in SO-24L Package

PIN FUNCTION DESCRIPTION

PACKAGE PIN #	PIN SYMBOL	FUNCTION
SO-24L		
1	SCLK	Serial clock for shifting in/out of data. Rising edge shifts data on SI into the shift register and the falling edge changes the data on SO.
2	CS	When High, allows data at SI to be shifted into the internal shift register with the rising edge of SCLK. The falling edge transfers the shift register contents into the DAC and multiplexer to update the output buffers. The falling edge also re-enables the output drivers if they have been disabled by a fault.
3	SIN-	Negative output for SINE coil.
4	SIN+	Positive output for SINE coil.
5, 6, 7, 8, 17, 18, 19, 20	GND	Ground for V_{BB} and V_{CC} supplies. In the power SOIC package they aid in removing internally generated heat from the package and as such should be soldered to as large a PCB area as possible.
9	$V_{BB}/2$	Set to $1/2 V_{BB}$ for biasing the two externally driven minor coils.
10	C1+	Positive output for the #1 minor coil.
11	C1-	Negative output for the #1 minor coil.
12	V_{CC}	5.0 V logic supply. The internal registers and latches are reset by a POR generated by the rising edge of the voltage on this lead.
13	FAULT	Reflects the state of the output buffers. A logic low on this lead indicates that an output is shorted or the device is in thermal shutdown.
14	V_{BB}	Analog supply. Nominally 12 V.
15	C2+	Positive output for the #2 minor coil.
16	C2-	Negative output for the #2 minor coil.
21	COS-	Negative output for COSINE coil.
22	COS+	Positive output for COSINE coil.
23	SI	Serial data input. Data present at the rising edge of the clock signal is shifted into the internal shift register.
24	SO	Serial data output. Existing 12 bit data is shifted out when new data is shifted in. Allows cascading of multiple devices on common serial port.

APPLICATIONS INFORMATION

THEORY OF OPERATION

The CS4122 is for interfacing between a microcontroller or microprocessor and air-core meters commonly used in automotive vehicles for speedometers, tachometers and auxiliary gauges. These meters are built using 2 coils placed at 90° orientation to each other. A magnetized disc floats in the middle of the coils and responds to the magnetic field generated by each coil. The disc has a shaft attached to it that protrudes out of the assembly. A pointer indicator is attached to this shaft and in conjunction with a separate printed scale displays the vehicle's speed, engine's speed or other information such as fuel quantity or battery voltage.

The disc (and pointer) respond to the vector sum of the voltages applied to the coils. Ideally, this relationship follows a sine/cosine equation. Since this is a transcendental and non-linear function, devices of this type use an approximation for this relationship. The CS4122 uses a tangential algorithm as shown in Figure 2 for the major (360°) gauge. Only one output varies in any 45° range.

Note: The actual slopes are segmented but are shown here as straight lines for simplicity.

Figure 2. Major Gauge Outputs

Quadrant I

$$\theta = \tan^{-1} \left[\frac{(V_{SIN+}) - (V_{SIN-})}{(V_{COS+}) - (V_{COS-})} \right]$$

For $\theta = 0.176^\circ$ to 44.824° :

$$V_{SIN} = \tan \theta \times 0.748 \times V_{BB}$$

$$V_{COS} = 0.748 \times V_{BB}$$

For $\theta = 45.176^\circ$ to 89.824° :

$$V_{SIN} = 0.748 \times V_{BB}$$

$$V_{COS} = \tan(90^\circ - \theta) \times 0.748 \times V_{BB}$$

Quadrant II

$$\theta = 180^\circ - \tan^{-1} \left[\frac{(V_{SIN+}) - (V_{SIN-})}{(V_{COS+}) - (V_{COS-})} \right]$$

For $\theta = 90.176^\circ$ to 134.824° :

$$V_{SIN} = 0.748 \times V_{BB}$$

$$V_{COS} = -\tan(\theta - 90^\circ) \times 0.748 \times V_{BB}$$

For $\theta = 135.176^\circ$ to 179.824° :

$$V_{SIN} = \tan(180^\circ - \theta) \times 0.748 \times V_{BB}$$

$$V_{COS} = -0.748 \times V_{BB}$$

Quadrant III

$$\theta = 180^\circ + \tan^{-1} \left[\frac{(V_{SIN+}) - (V_{SIN-})}{(V_{COS+}) - (V_{COS-})} \right]$$

For $\theta = 180.176^\circ$ to 224.824° :

$$V_{SIN} = -\tan(\theta - 180^\circ) \times 0.748 \times V_{BB}$$

$$V_{COS} = -0.748 \times V_{BB}$$

For $\theta = 225.176^\circ$ to 269.824° :

$$V_{SIN} = -0.748 \times V_{BB}$$

$$V_{COS} = -\tan(270^\circ - \theta) \times 0.748 \times V_{BB}$$

Quadrant IV

$$\theta = 360^\circ - \tan^{-1} \left[\frac{(V_{SIN+}) - (V_{SIN-})}{(V_{COS+}) - (V_{COS-})} \right]$$

For $\theta = 270.176^\circ$ to 314.824° :

$$V_{SIN} = -0.748 \times V_{BB}$$

$$V_{COS} = \tan(\theta - 270^\circ) \times 0.748 \times V_{BB}$$

For $\theta = 315.176^\circ$ to 359.824° :

$$V_{SIN} = -\tan(360^\circ - \theta) \times 0.748 \times V_{BB}$$

$$V_{COS} = 0.748 \times V_{BB}$$

Figure 3. Major Gauge Response

The minor gauge coil outputs differ in that only one of the coils in each movement is driven by the IC. The other is driven directly by the analog supply voltage, specifically one-half of this voltage. The common output assures that this is true. By varying the voltage across the other coil to a greater voltage, the pointer can be deflected more than 45° to each side of the externally driven coil. This relationship is shown in Figure 4.

Note: There are actually 8 segments, but only 3 are shown here for simplicity.

Figure 4. Minor Gauge Outputs

Quadrant I, II

$$\theta = 56.1^\circ - \tan^{-1} \left[\frac{(V_{C+}) - (V_{C-})}{V_{BB} - V(V_{BB}/2)} \right]$$

$$V_{COIL} = V(V_{BB}/2) \times \tan(56.1^\circ - \theta)$$

Figure 5. Minor Gauge Outputs

To drive a gauge's pointer to a particular angle, the microcontroller sends a 12 bit digital word to the CS4122. These 12 bits are divided as shown in Figure 6. However, from a software programmer's viewpoint, a 360° circle is divided into 1024 equal parts of .35° each and a 112.2° arc is divided into 256 parts of .44° each. Table 1 shows the data associated with the 45° divisions of the 360° driver. Table 2 shows the data for the center and end points of the 112.2° drivers. Setting the address to "11" disables all outputs.

Table 2. Nominal Output for Minor Gauges (V_{BB} = 14 V)

Input Code (Decimal)	Scale Degrees	Degrees from Center	V _{COIL}
0	0	-56.1	10.417
127	55.88	-0.22	0.027
128	56.32	0.22	-0.027
255	112.2	56.1	-10.417

The 12 bits are shifted into the device's shift register MSB first using a SPI compatible scheme. This method is shown in Figures 6 and 7. The first 2 bits select the output driver for which the data is intended. The CS must be high and remain high for SCLK to be enabled. Data on SI is shifted in on the

rising edge of the synchronous clock signal. Data in the shift register is shifted to SO on the falling edge of SCLK. This arrangement allows the cascading of devices. SO is always enabled. Data shifts through without affecting the outputs until CS is brought low. At this time, the internal DAC is updated and the outputs change accordingly.

Figure 7. Serial Data Timing Diagram

The DAC for the major gauge driver outputs 128 discrete levels selected by bits D6 – D0. These bits are XOR'd with D7 to invert them when choosing the 2nd half of each quadrant (each odd octant). This reduces the number of

resistors and switches required. The MUX chooses which signals to send to the output amplifiers based upon D9 – D7. There are three choices for each amplifier: high, low or the DAC output.

The DAC's for the minor gauge drivers similarly output 128 discrete levels selected by bits D6 – D0. These bits are also XOR'd with D7 to invert them when choosing the 2nd half of the output range. The MUX chooses which signals to send to the output amplifiers based upon D7. There are two choices for each amplifier; high or the DAC output. Bits D8 and D9 are not used, but should be set to "00" to ensure that the minor gauge outputs are enabled.

The output buffers are unity gain amplifiers. Each of the 8 outputs is designed to swing close to the supply rails to maximize the voltage across the coils to produce maximum torque. Additionally, this lowers the power dissipation. The current for each output is also monitored. If any of the major gauge outputs exceed the maximum value, all of the major outputs are disabled. If any of the minor gauge outputs exceed the maximum value, all of the minor outputs are disabled. The falling edge of the CS re-enables the outputs with the fault condition but they remain on only if the overcurrent situation has been eliminated.
